

# Precision matrix estimation in Gaussian graphical models

Michał Makowski

Wydział Matematyki i Informatyki  
Uniwersytet Wrocławski

*m.makowski@aol.com*

# Presentation plan

## 1 Overview

- Intuition and examples
- Background
- Implementation
- Results

## 2 Theory

- Factorization
- Multiple testing
- Alternating direction method of multipliers

## 3 Even more theory

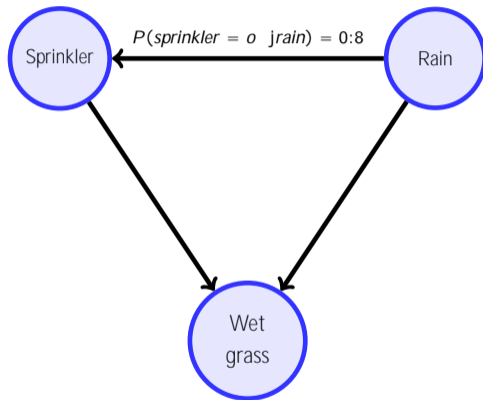

A graphical models theory generalizes and is able to describe a broad range of statistical models

- Markov models/hidden Markov models
- Bayesian networks
- Kalman filters
- neural networks

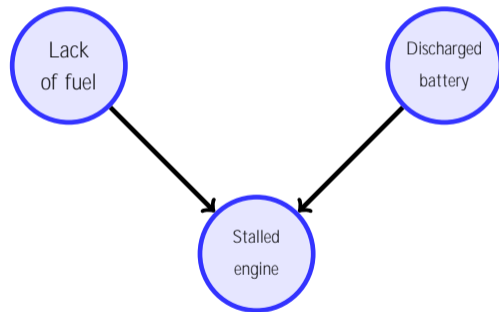

Graphical models bound probability and graph theory

- probability - uncertainty/randomness
- graph theory - dependence/correlation

# Directed graph

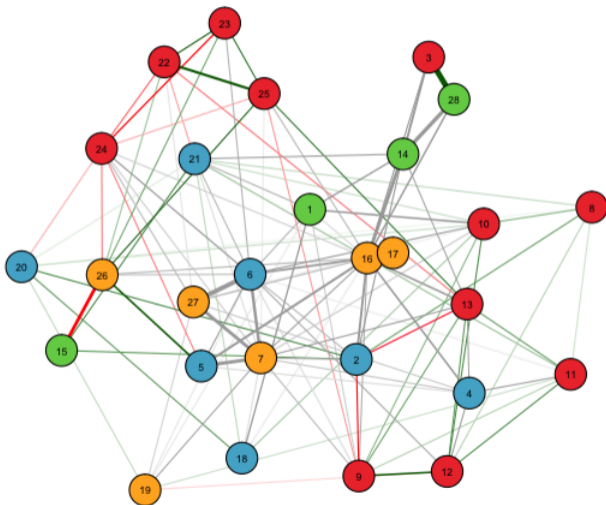

(a) 'Garden' model

(b) 'Car' model

# Undirected graph [1/3]

- **Demographics**

  - 25: Satisfaction: Education

# Undirected graph [2/3]

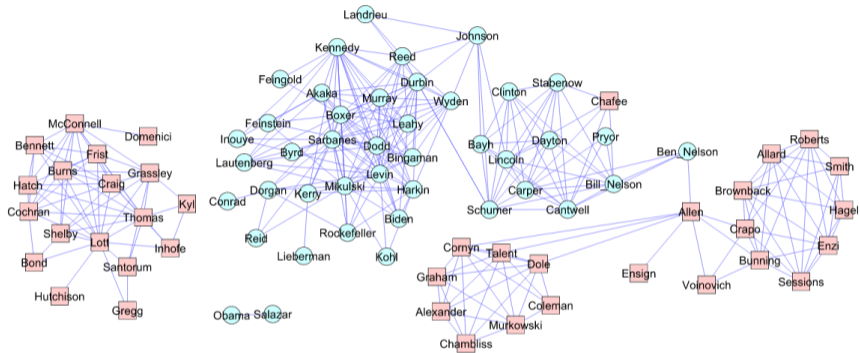

Figure 16: US Senate, 109th Congress (2004-2006). The graph displays the solution to (12) obtained using the log determinant relaxation to the log partition function of Wainwright and Jordan (2006). Democratic senators are represented by round nodes and Republican senators are represented by square nodes.

# Undirected graph [3/3]

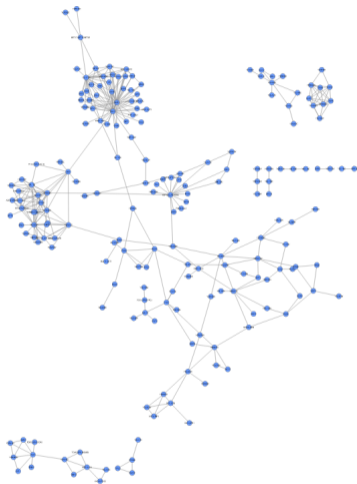

Figure 13: Application to Hughes compendium. The above graph results from solving (1) for this data set with a penalty parameter of  $\lambda = 0.0313$ .

## Gaussian distribution factorization

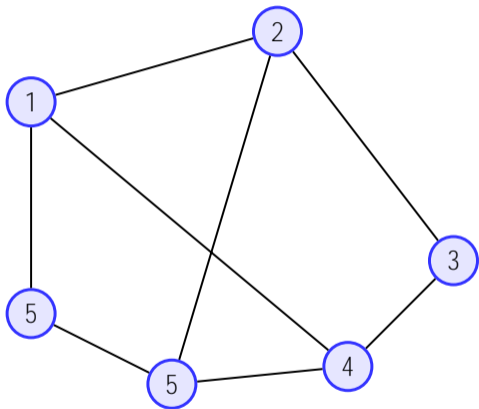

Any multivariate normal distribution  $N(\mu; \Sigma)$  can be parameterized by canonical parameters in the form

$$\eta = \Sigma^{-1} \mu \quad \text{and} \quad \theta = \Sigma^{-1}:$$

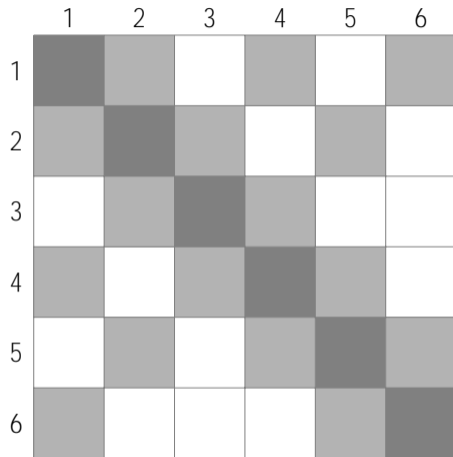

If  $X \sim N(\mu; \Sigma)$  factorizes according to some graph  $G$ , then  $\theta_{st} = 0$  for any pair  $(s; t) \not\in E$ .

This sets up correspondence between the zero pattern of the matrix  $\theta$  and pattern of the underlying graph. In particular, if the  $\theta_{st} = 0$ , then variables  $s$  and  $t$  are conditionally independent, given the other variables.

# Graph and matrix correspondence

(c) The undirected graph  $G$  on six vertices.

(d) The associated sparsity pattern of the precision matrix. White squares correspond to zero entries.

Let  $\mathbf{S}$  be a sample covariance matrix.

## MLE

$$\hat{\Sigma}_{ML} = \arg \max_{\Sigma \in \mathcal{S}_+^p} \log \det \Sigma - \text{tr}(\mathbf{S} \Sigma^{-1})$$

MLE exists if the matrix  $\mathbf{S}$  is nonsingular. Then the solution to problem above is simply given by

$$\hat{\Sigma}^{-1} = \mathbf{S};$$

If a number of variables  $p$  is comparable or greater than a number of observations  $N$ , then the sample covariance matrix  $\mathbf{S}$  is singular, thus the MLE does not exist.

Moreover, it is obvious that  $P(\mathcal{G}_{i;j} \hat{\gamma}_{ij} = 0) = 0$ , but in many applications a *sparse* solution is demanded.

# Regularization

The number of edges can be controlled by the  $\ell_0$ -based quantity

$$\ell_0(\mathbf{S}) = \sum_{s \neq t} \mathbb{1}[s_{st} \neq 0]:$$

Note that  $\ell_0(\mathbf{S}) = 2|E(G)|$  for a given graph  $G$ .

## $\ell_0$ -based problem

$$\hat{\mathbf{S}} = \underset{\substack{\mathbf{S} \in \mathcal{S}_+^p \\ \ell_0(\mathbf{S}) \leq k}}{\arg \max} \log \det \mathbf{S} - \text{tr}(\mathbf{S} \mathbf{g})$$

Unfortunately, the  $\ell_0$ -based constraint defines a highly nonconvex constraint set, what makes the problem hard to solve.

Convex relaxation of  $\ell_0$ -based constrain leads to

$$L(\mathbf{S}; X) = \log \det \mathbf{S} - \text{tr}(\mathbf{S} X) - F(\mathbf{S}):$$

where  $F(\cdot)$  denotes any convex function, which might be applied in the considered problem.

## Main motivation - FDR control

A performance of every binary classifier could be summarized in a confusion matrix

		Real value	
		(+)	(-)
Test outcome	(+)	True positive	False positive
	(-)	False negative	True negative

### (Local) False discovery rate (FDR)

$$\text{FDR} = \mathbb{E} \left[ \frac{\#[\text{False positive}]}{\#[\text{False positive}] + \#[\text{True positive}]} \right]$$

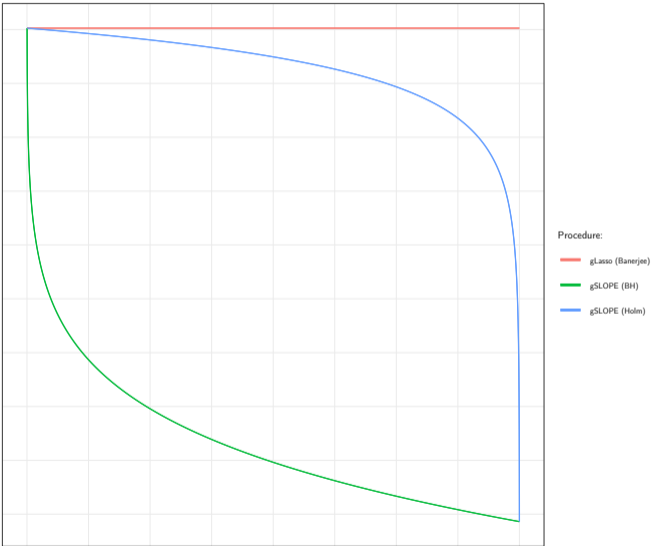

$$\text{localFDR} = \mathbb{E} \left[ \frac{\#[\text{False positive outside the component}]}{\#[\text{False positive}] + \#[\text{True positive}]} \right]$$

## Lambda based on multiple testing theory

- gLasso - Bonferonni correction (Banerjee et. al.)
- gSLOPE - Holm method
- gSLOPE - Benjamini-Hochberg procedure

# Lambda comparison

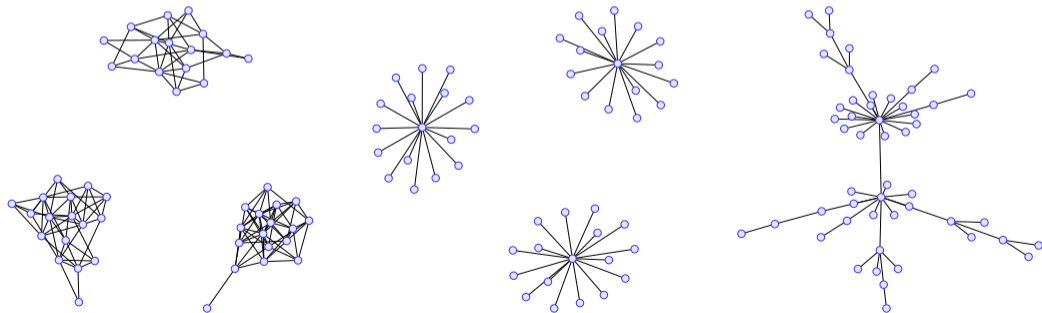

For solving the Graphical SLOPE problem we used the *Alternating direction method of multipliers*, it can solve convex problems in the form

$$\begin{aligned} & \text{minimize} && f(x) + g(y) \\ & \text{subject to} && Ax + By = c: \end{aligned}$$

For solving the Graphical Lasso problem we used an algorithm proposed by Friedman et al. in their first work about this method. Although we derived an ADMM-based algorithm, it was orders of magnitude slower than original one.

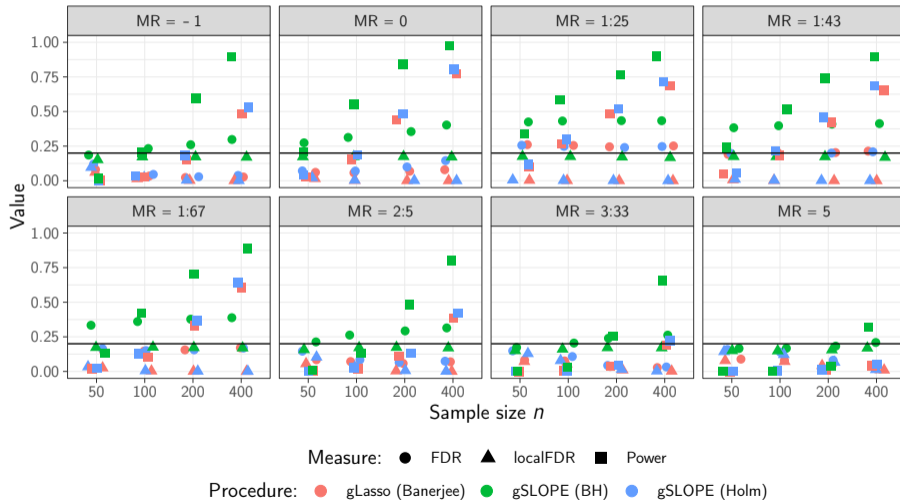

# Implementation overview

- Implementation with R, the huge package for simulations.
- Various types of graphs structure: cluster, hub, and scale-free.
- Data:  $p = 100$ ,  $n \in \{50; 100; 200; 400\}$ ; different magnitude ratios; different sparsity and size of components.
- Two levels of a desirable FDR control: 0:05 and 0:2 .

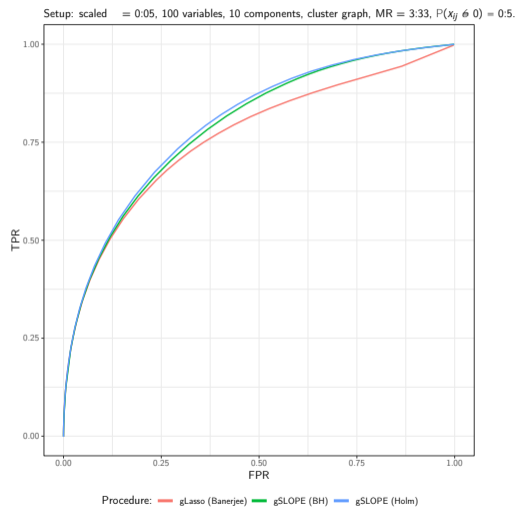

# Cluster results

Setup:  $\rho = 0.2$ , 100 variables, 10 components, cluster graph,  $P(x_{ij} \neq 0) = 0.5$ .

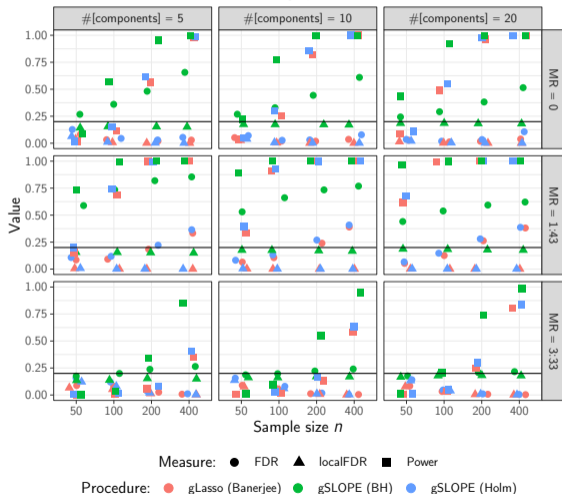

# Cluster ROC

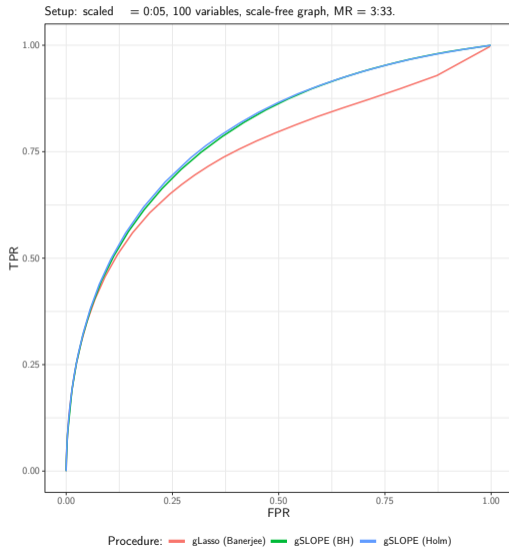

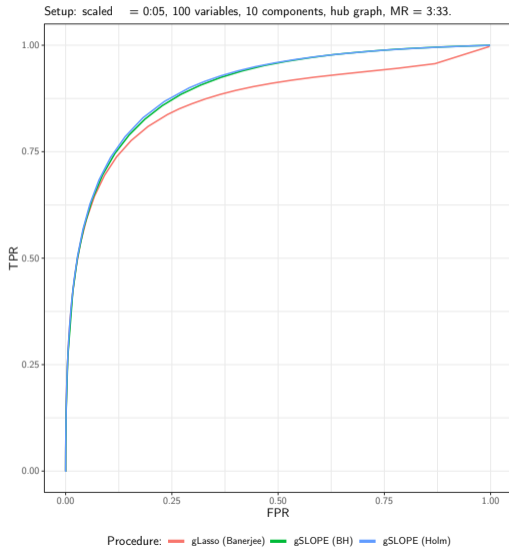

# Hub results

Setup:  $\rho = 0.2$ , 100 variables, hub graph.

# Non-cluster ROC

Let's go deeper into theory...

## Conditional independence

Two random variables  $X, Y$  are conditionally independent *wrt* random vector  $\mathbf{Z} = (Z_1; \dots; Z_n)^T$  if their distributions are independent *wrt*  $\mathbf{Z}$ .

This relationship is denoted by symbol  $\perp\!\!\!\perp$ .

Formally, for all triples  $x; y; \mathbf{z}$

$$(X \perp\!\!\!\perp Y) \mid \mathbf{Z} \iff F_{X;Y \mid \mathbf{Z}=\mathbf{z}}(x; y) = F_{X \mid \mathbf{Z}=\mathbf{z}}(x) F_{Y \mid \mathbf{Z}=\mathbf{z}}(y);$$

where  $F_{X;Y \mid \mathbf{Z}=\mathbf{z}}(x; y)$  is the conditional CDF of  $X$  and  $Y$  for a given  $\mathbf{Z}$ .

## Conditional independence and graph structure

For a family of multivariate probability distributions there could be constructed a graph which constraints a PDF factorization and the conditional independence property

node  $A$  is not connected with node  $B$   $(\ )$   $X_A \perp\!\!\!\perp X_B \mid X_{-AB}$ ;

where  $X_{-AB}$  denotes all random variables except  $X_A$  and  $X_B$ .

## Conditional independence and precision matrix

Canonical parameterization of Multivariate Gaussian Distribution constraint a precision matrix and a conditional independence property.

Let  $(X_1, \dots, X_n) \sim N(\mu; \Sigma)$ , then

$$X_s \perp\!\!\!\perp X_t \mid X_{-st} \iff \Sigma_{st} = 0;$$

where  $X_{-st}$  denotes all random variables except  $X_s$  and  $X_t$ .

## Graph structure and precision matrix

There is connection between an underlying graph and a precision matrix structure

node  $S$  is not connected with node  $T$   $(S, T) \in E \iff \Sigma_{st} = 0;$

where  $s$  and  $t$  are variable indexes of Multivariate Gaussian Distribution.

# Multiple testing

## Bonferroni correction

The Bonferroni correction rejects the null hypothesis for each  $p_i \leq \frac{\alpha}{m}$ , thereby controls the FWER at level  $\alpha$ , that is  $\text{FWER} \leq \alpha$ . No other assumptions are required.

## Holm method

Sort p-values ascending and reject the first hypothesis for which  $p_{(k)} > \frac{\alpha}{m+1-k}$  is true, then reject every hypothesis before. Holm method controls FWER at level  $\alpha$ .

## Benjamini-Hochberg method

Sort p-values ascending and find first the hypothesis for which  $p_{(k)} \leq \frac{k}{m} \alpha$  is true, then reject every hypothesis before. BH method controls FDR at level  $\alpha$ .

The convex relaxation of  $\ell_0$ -based constrain leads to

$$L(S; X) = \log \det S - \text{tr}(SX) - \sum_i k_i \|S_{ii}\|_1:$$

where  $\sum_i k_i \|S_{ii}\|_1$  denotes entrywise off-diagonal  $\ell_1$ -norm  $\|kA\|_1 = \sum_{i \neq j} |a_{ij}|$ .

## Graphical Lasso problem

$$\hat{S} = \arg \max_{S \in \mathcal{S}_+^p} \log \det S - \text{tr}(SX) - \sum_i k_i \|S_{ii}\|_1:$$

## Banerjee lambda for Graphical Lasso

$$\lambda_{\text{Banerjee}}(\alpha) = \max_{i < j} (s_{ij}; s_{jj}) \frac{qt_{n-2}(1 - \frac{\alpha}{2p^2})}{\sqrt{n-2 + qt_{n-2}^2(1 - \frac{\alpha}{2p^2})}} \quad (1)$$

The following theorem was formulated by Banerjee et al.

## Theorem

Using (1) as the penalty parameter in Graphical Lasso problem, for any fixed level  $\alpha$  we obtain

$$P(\text{False Discovery}) \leq \alpha :$$

# SLOPE

In the [Bog+15] Bogdan et al. proposed novel approach for regularization in regression analysis. SLOPE uses the *OL1* norm instead of the *L1* norm for a coefficient choice.

## *OL1* norm

Penalty based on sorted  $\ell_1$  (known as *OL1*, *OWL* or *OSCAR*) for  $\beta \in \mathbb{R}^p$  and  $\lambda_1 > \dots > \lambda_p$  is defined as

$$J(\beta) = \sum_{i=1}^p \lambda_i |\beta_{(i)}|$$

It was shown that under some assumptions and a construction of  $\lambda_i$  parameters based on BH procedure, proposed method controls FDR in multivariate regression settings.

# Graphical SLOPE

In the graphical SLOPE the  $L1$  norm from a graphical Lasso algorithm is changed for the off-diagonal  $OL1$  norm

$$L(\beta; X) = \log \det \Sigma - \text{tr}(\mathbf{S} \Sigma) - J(\beta):$$

## Graphical SLOPE problem

$$\hat{\beta} = \arg \max_{\Sigma \in \mathcal{S}_+^p} \log \det \Sigma - \text{tr}(\mathbf{S} \Sigma) - J(\beta);$$

In the [Sob19] P. Sobczyk showed that  $OL1$  brings promising results in terms of a FDR control.

### Holm lambda for Graphical SLOPE

$$m = \frac{p(p-1)}{2};$$
$$\text{Holm}_k = \frac{qt_{n-2}(1 - \frac{k}{m})}{\sqrt{n-2 + qt_{n-2}^2(1 - \frac{k}{m})}};$$
$$\text{Holm} = f_{1}^{\text{Holm}_1}, f_{2}^{\text{Holm}_2}, \dots, f_{m}^{\text{Holm}_m} g;$$

It is based on the Holm method for the multiple testing.

### BH lambda for Graphical SLOPE

$$m = \frac{p(p-1)}{2};$$
$$\frac{BH}{k} = \frac{qt_{n-2}(1 - \frac{1}{m+1-k})}{\sqrt{n-2 + qt_{n-2}^2(1 - \frac{1}{m+1-k})}};$$
$$BH = f \left( \frac{BH}{1}, \frac{BH}{2}, \dots, \frac{BH}{m} \right);$$

It is based on the Benjamini-Hochberg procedure for the multiple testing.

The alternating direction method of multipliers (ADMM) is an algorithm that solves convex optimization problems by breaking them into smaller pieces, each of which are then easier to handle.

The precursors of ADMM

- Dual Ascent and Dual Decomposition algorithms (decomposability properties)
- Method of multipliers (convergence properties)

The ADMM algorithm can solve problems in the form

$$\begin{aligned} & \text{minimize} && f(x) + g(y) \\ & \text{subject to} && Ax + By = c; \end{aligned}$$

where convexity of functions  $f$  and  $g$  is assumed.

Augmented Lagrangian with parameter  $\rho > 0$  is defined as

$$L(x; y; \nu) = f(x) + g(y) + \nu^T (Ax + By - c) + \frac{\rho}{2} \|Ax + By - c\|^2;$$

---

**Algorithm 1** Alternative direction method of multipliers

---

```

 $y_0 \leftarrow \tilde{y}, \nu_0 \leftarrow \tilde{\nu}, k \leftarrow 1$ 
 $\mu \leftarrow \tilde{\rho} > 0$  ▷ initialize
while convergence criterion is not met do
   $x_k \leftarrow \arg \min_x L_\rho(x, y_{k-1}, \nu_{k-1})$  ▷ x-minimization
   $y_k \leftarrow \arg \min_y L_\rho(x_k, y, \nu_{k-1})$  ▷ y-minimization
   $\nu_k \leftarrow \nu_{k-1} + \rho(Ax_k + By_k - b)$  ▷ dual update
   $k \leftarrow k + 1$ 
end while

```

---

Optimisation problem for graphical SLOPE is in the form

$$\begin{aligned} & \text{minimize} && -\log \det \mathbf{S} + \text{tr}(\mathbf{S}^{-1}) + I(\mathbf{S} \succeq 0) + J(Y) \\ & \text{subject to} && Y = \mathbf{X} \mathbf{S}^{-1} \mathbf{X}^T : \end{aligned}$$

Augmented Lagrangian  $L : \mathbb{R}^{p \times p} \times \mathbb{R}^{p \times p} \times \mathbb{R}^{p \times p} \rightarrow \mathbb{R}$  with parameter  $\lambda > 0$  is given by

$$\begin{aligned} L(X; Y; N) = & -\log \det \mathbf{S} + \text{tr}(\mathbf{S}^{-1}) + I(\mathbf{S} \succeq 0) + J(Y) + \\ & \lambda \text{tr}(N; \mathbf{S}^{-1} - Y) + \frac{\lambda}{2} \text{tr}(\mathbf{S}^{-1} - Y)^2 : \end{aligned}$$

Let's dive even deeper...

# Factorization theorem

## Compatibility function

Let  $G = (V; E)$  be a graph with a vertex set  $V = \{1; 2; \dots; p\}$  and  $\mathcal{C}$  be its clique set. Let  $X = (X_1; \dots; X_p)$  be a random vector defined on a probability space  $(\Omega; \mathcal{F}; \mathbb{P})$ , indexed by the graph nodes.

### Definition (Compatibility function)

Let  $C \in \mathcal{C}$  be a clique of the graph  $G$  and let  $X_C$  be a subvector of the vector  $X$  indexed by the elements of the clique  $C$ , that is  $X_C = (X_s; s \in C)$ . A real-valued function  $\psi_C$  of the vector  $X_C$  taking positive real values is called a *compatibility function*.

## Factorization property

### Definition (Factorization)

Let  $C \subseteq \mathcal{C}$  be a clique of the graph  $G$  and let  $X_C$  be a subvector of the vector  $X$  indexed by the elements of the clique  $C$ , that is  $X_C = (X_s; s \in C)$ . A real-valued function  $c_C$  of the vector  $X_C$  taking positive real values is called a *compatibility function*.

Given a collection of compatibility functions, we say that probability distribution  $P$  *factorizes over  $G$*  if it has decomposition

$$P(x_1; \dots; x_n) = \frac{1}{Z} \prod_{C \subseteq \mathcal{C}} c_C(x_C); \quad (2)$$

where  $Z$  is the normalizing constant, known as the *partition function*. It is given by

$$Z = \sum_x \prod_{C \subseteq \mathcal{C}} c_C(x_C); \quad (3)$$

where the sum goes over all possible realizations of  $X$ .

Consider a cut set  $S$  of the given graph and let introduce a symbol  $\perp\!\!\!\perp$  to denote the relation *is conditionally independent of*. With this notation, we say that the random vector  $X$  is Markov with respect to  $G$  if

$$X_A \perp\!\!\!\perp X_B \mid X_S \quad \text{for all cut sets } S \subseteq V; \quad (4)$$

where  $X_A$  denotes the subvector indexed by the subgraph  $A$ .

# Canonical formulation

## Canonical formulation

Any nondegenerated multivariate normal distribution  $N(\mu; \Sigma)$  can be reparameterized into canonical parameters in the form

$$\eta = \Sigma^{-1} \mu \quad \text{and} \quad \theta = \Sigma^{-1};$$

Then density function is given by

$$P; \mu(x) = \exp \left[ \sum_{s=1}^p \eta_s x_s - \frac{1}{2} \sum_{s,t=1}^p \theta_{st} x_s x_t - A(\eta; \theta) \right];$$

where  $A(\eta; \theta) = -\frac{1}{2} \left( \det[(2\theta)^{-1}] + \eta^T \theta^{-1} \eta \right)$ .

## Canonical formula derivation

$$\begin{aligned}
 P ; (x) &= \left( \sqrt{\det[2^{-1}]} \right)^{-1} \exp \left( -\frac{1}{2} (x - \mu)^T \Sigma^{-1} (x - \mu) \right) \\
 &= \left( \sqrt{\det[(2 \Sigma)^{-1}]} \right) \exp \left( -\frac{1}{2} x^T \Sigma^{-1} x + x^T \Sigma^{-1} \mu - \frac{1}{2} \mu^T \Sigma^{-1} \mu \right) \\
 &= \left( \sqrt{\det[(2 \Sigma)^{-1}]} \right)^{-1} \exp \left( -\frac{1}{2} x^T \Sigma^{-1} x + x^T \Sigma^{-1} \mu - \frac{1}{2} \mu^T \Sigma^{-1} \mu \right) \\
 &= \exp \left( -\frac{1}{2} x^T \Sigma^{-1} x + x^T \Sigma^{-1} \mu - \frac{1}{2} (\mu^T \Sigma^{-1} \mu) \right) \\
 &= \exp \left( -\frac{1}{2} x^T \Sigma^{-1} x + x^T \Sigma^{-1} \mu - A(\mu ; \Sigma) \right) \\
 &= P ; (x)
 \end{aligned}$$

# Log-likelihood derivation

## Log-likelihood derivation (1/2)

$$\begin{aligned}L(\boldsymbol{\theta}; \mathbf{X}) &= \frac{1}{N} \sum_{i=1}^N \log P(x_i) \\&= \frac{1}{N} \sum_{i=1}^N \left[ -\frac{1}{2} x_i^T \boldsymbol{\theta} - A(\boldsymbol{\theta}) \right] \\&= \frac{1}{N} \sum_{i=1}^N \left[ \frac{1}{2} \log \det[(2\boldsymbol{\theta}^T \boldsymbol{\theta})^{-1}] - \frac{1}{2} x_i^T \boldsymbol{\theta} \right] \\&= \frac{1}{2N} \sum_{i=1}^N \log \left( (2\boldsymbol{\theta}^T \boldsymbol{\theta})^{-N} \det[\mathbf{I}] \right) - x_i^T \boldsymbol{\theta} \\&= \frac{1}{2N} \sum_{i=1}^N \log \det \boldsymbol{\theta} - N \log 2 - x_i^T \boldsymbol{\theta} \quad x_i = \dots\end{aligned}$$

## Log-likelihood derivation (2/2)

$$\begin{aligned} \dots &= \frac{1}{2N} \sum_{i=1}^N \log \det \begin{pmatrix} 2 & x_i^T \\ x_i & \mathbf{S} \end{pmatrix} - N \log 2 - \frac{1}{2} \text{tr} \begin{pmatrix} 2 & x_i^T \\ x_i & \mathbf{S} \end{pmatrix} \\ &= \frac{1}{2N} \sum_{i=1}^N \log \det \begin{pmatrix} 2 & x_i^T \\ x_i & \mathbf{S} \end{pmatrix} - N \log 2 - \frac{1}{2} \text{tr} \begin{pmatrix} 2 & x_i^T \\ x_i & \mathbf{S} \end{pmatrix} \\ &= \frac{1}{2} \log \det \begin{pmatrix} 2 & x_i^T \\ x_i & \mathbf{S} \end{pmatrix} - \frac{N}{2} \log 2 - \frac{1}{2N} \sum_{i=1}^N \text{tr} \begin{pmatrix} 2 & x_i^T \\ x_i & \mathbf{S} \end{pmatrix} \\ &= \frac{1}{2} \log \det \begin{pmatrix} 2 & x_i^T \\ x_i & \mathbf{S} \end{pmatrix} - \frac{N}{2} \log 2 - \frac{1}{2} \text{tr}(\mathbf{S}); \end{aligned}$$

where  $\mathbf{S}$  is an empirical covariance matrix given by  $\frac{1}{N} \sum_{i=1}^N x_i x_i^T$ .

# ADMM for Graphical SLOPE

## Graphical SLOPE problem - ADMM formulation

$$\begin{aligned} & \text{minimize} && -\log \det X + \text{tr}(XS) + I[X \succeq 0] + J(Y) \\ & \text{subject to} && X = Y: \end{aligned}$$

## Graphical SLOPE problem - Augmented Lagrangian

$$\begin{aligned} L(X; Y; N) = & -\log \det X + \text{tr}(XS) + I[X \succeq 0] \\ & + k\|Y\|_{k_1} + hN; X - Y|_F + \frac{k}{2}\|X - Y\|_F^2 \end{aligned}$$

## X-update (1/3)

We have

$$X_k = \arg \min_X L(X; Y_{k-1}; N_{k-1}) = \arg \min_{X \succ 0} -\log \det X + \frac{1}{2} \|X - \tilde{S}_{k-1}\|_F^2 ;$$

where

$$\tilde{S}_{k-1} = -N_{k-1} + Y_{k-1} - \frac{1}{2} S;$$

The  $X$ -gradient of the augmented Lagrangian is given by

$$r_X L(X; Y_{k-1}; N_{k-1}) = -X^{-1} + X - \tilde{S}_{k-1};$$

As the augmented Lagrangian is convex, it is clear that for some  $X \succ 0$

$$r_X L(X; Y_{k-1}; N_{k-1}) = -X^{-1} + X - \tilde{S}_{k-1} = 0:$$

## X-update (2/3)

Rewriting equation as

$$-(X)^{-1} + X = \tilde{S}_{k-1};$$

we can find a matrix that meets this condition.

At first, let's take the eigenvalue decomposition of right side

$$\tilde{S}_{k-1} = Q Q^T;$$

Then by multiplying right and left side by  $Q$  and  $Q^T$  respectively, we obtain

$$-(\tilde{X})^{-1} + \tilde{X} = ;$$

where  $\tilde{X} = Q^T X Q$ .

## X-update (3/3)

We have to find positive numbers  $\tilde{x}_{ij}$  that satisfy

$$(\tilde{x}_{ij})^2 - l_{ij}\tilde{x}_{ij} - \frac{1}{2} = 0:$$

It is obvious that

$$\tilde{x}_{ij} = \frac{l_{ij} + \sqrt{l_{ij}^2 + 4}}{2}:$$

Thus  $X$  is given by  $X = Q^T \tilde{X} Q$ . All diagonals are positive since  $\tilde{x}_{ij} > 0$ . Define  $F(\cdot)$  as

$$F(\cdot) = \frac{1}{2} \text{diag} \left( l_i + \sqrt{l_i^2 + 4} \right) :$$

Since that

$$X = Q^T \tilde{X} Q = Q^T F(\cdot) Q = F(\tilde{S}_{k-1}) = F\left(-N_{k-1} + Y_{k-1} - \frac{1}{2}S\right);$$

we obtain a formula for updating  $X_k$  in each step.

A formula for  $Y_k$  is different. We have

$$\begin{aligned} Y_k &= \arg \min_Y L(X_k; Y; N_{k-1}) \\ &= \arg \min_Y J(Y) + \frac{\lambda}{2} \|Y - (X_k + N_{k-1})\|_F^2 \end{aligned}$$

The last line of Y-update can be represented as a proximity operator which has closed form formula for SLOPE

$$\arg \min_Y J(Y) + \frac{\lambda}{2} \|Y - (X_k + N_{k-1})\|_F^2 = \text{prox}_J; (X_k + N_{k-1}): \quad (5)$$

---

**Algorithm 4** Alternative direction method of multipliers for gSLOPE

---

 $Y_0 \leftarrow \tilde{Y}, N_0 \leftarrow \tilde{N}, k \leftarrow 1$ 

▷ initialize (loosely)

 $\mu \leftarrow \tilde{\mu} > 0$ 

▷ initialize

**while** convergence criterion is not meet **do** $X_k \leftarrow \mathcal{F}_\rho(N_{k-1} + Y_{k-1} - \frac{1}{\rho}S)$ 

▷ x-minimization

 $Y_k \leftarrow \text{prox}_{J_{\lambda,\rho}}(X_k + N_{k-1})$ 

▷ y-minimization

 $N_k \leftarrow N_{k-1} + \rho(X_k - Y_k)$ 

▷ dual update

 $k \leftarrow k + 1$ **end while**

---

Thank you for your attention
